Introduction
Bakanae disease caused by *Fusarium fujikuroi* Nirenberg [F. *moniliforme* (Sheld.), telomorph: Gibberella fujikuroi Sawada, Wollenweber] emerged as a significantly important disease in recent times in Asia and other rice growing countries of the world (Singh and Sunder, 2012). Rice is one of the world’s most favored staple foods grain and about more than 90% of the world’s rice is produced and consumed in Asian countries (Singh et al., 2013). In India, the total area under rice cultivation during the year 2013 was 43.52 million hectares with annual production of 159.20 million tons of paddy with an average productivity of 3.59 t/ha (FAO stat 2014). In Haryana, bakanae has attained the status of a major disease after its first record since kharif 1988 particularly on scented tall varieties (Dodan et al. 1997). A highly positive correlation (r = 0.999) has been established between disease incidence and loss in grain yield of paddy (Sunder et al. 1997). Higher rice yield can only be obtained through improved cultivars and integrated crop and pest management technologies (FAO, 1995; Kumar et al., 2013; Prajapati et al., 2013). Now-adays, the scenario of rice diseases is changing due to extensive use of fertilizers, irrigations, pesticides and high yielding cultivars. The minor diseases like, false smut, bakanae, sheath rot and grain discoloration which were of less significance earlier, are now emerging as serious threat to rice cultivation. *F. moniliforme* is primarily a seed-borne pathogen which infects the seedlings at the time of germination or at an early growth stage (Ou 1985). Injured roots have been reported to serve as potential entry source of *Fusarium* spp. in different crops. In rice, injury to the roots mainly occurs during nursery uprooting depending upon the soil moisture. The incidence of bakanae disease has increased steadily, particularly on aromatic rice cultivars in all rice growing states of India which causes severe qualitative and quantitative yield losses to rice crop (Bashyal et al., 2014; Gupta et al., 2014). Some fungicides particularly the organomercurials and benzimidazoles have been reported to be effective in suppressing the fungal growth in vitro and bakanae incidence in field (Kauraw 1981, Sunder et al. 1998). The research on bakanae disease and its sustainable management are the need of the hour and must be given top priority for disease free quality seed production, realizing higher yield potential of aromatic rice and to get edge in rice trade at international market before it is too late.
**History:** Bakanae disease was first identified during 1828 in Japan. Hori Shotaro (1898) first time demonstrated the fungus *Fusarium heterosporum* Nees induced the bakanae symptom in rice plants. It was later put in the genus *Gibberella* under the name *G. fujikuroi* (Sawada) (Ito and Kimura, 1931). There has been disagreement among plant pathologists for the nomenclature of bakanae fungus. In 1930s, the imperfect stage of the fungus was described by H.W.Wollenweber (1935) as *Fusarium moniliforme* (Sheldon) and the perfect stage *Gibberella fujikuroi* (Sawada) Wr. The terms ‘Fujikuroi’ and ‘Saw’ in *G. fujikuroi* (Sawada) Wr. were derived from the name of two distinguished Japanese plant pathologists, Yosaburo Fujikuro and Kenkichi Sawada (Watanabe and Umehara, 1997). In India, the prevalence and incidence of bakanae disease has been reported particularly on basmati rice cultivars (Bashyal et al., 2014; Gupta et al., 2014).

- **Geographical distribution and economic significance:** The yield losses ranging from 15-25% have been reported from Uttar Pradesh, Assam, Andhra Pradesh, Tamilnadu, Haryana and Punjab states of India. (Pavgi and Singh, 1964; Rathaiiah et al., 1991; Pannu et al., 2012; Sunder et al., 2014). Bakanae, is, therefore, a major concern in the affected rice growing areas of India and also becoming more alarmed threat for sustainable rice production in other parts of the rice growing world. Apart from yield losses studies, the bakanae pathogen was also found to be associated in highest percentage (1-24%) in seeds of different basmati rice cultivars (Butt et al., 2011; Bashyal and Aggarwal, 2013) and showed the profound effect of the disease on seed quality. The observations and surveys from 2008-2014 in Northern states of India also showed the incidence of bakanae disease ranged from 1.2-40%, especially in basmati rice cultivars (Gupta et al., 2014).

**Symptomatology:** Bakanae disease of rice is also known as “foot rot” in India, “white stalk” in China, “man rice” in the Philippines and “bakanae-byo or elongation disease” in Japan. Bakanae is a Japanese word which means bad or naughty seedling referring to the abnormal elongation, “thin noodle seedling”, “foolish seedling” or “stupid rice crop” (Sun and Snyder, 1981). The bakanae infected seedlings appeared as taller with chlorotic stems and leaves which become yellowish green to pale in colour in later stages. Diseased plants showed yellowish green elevated flag leaves with more horizontal orientation. The disease can build up in a crop very fast and a field with bakanae will remain uneven throughout the growing season. Therefore, it can be observed in nursery beds as well as in field from a distance (Fig. A).

**Host range of the pathogen Primary hosts:** Primary hosts of bakanae pathogen have been reported as rice, maize, barley, sorghum, sugarcane, wheat, pine, rye and asparagus from Asia, Africa, South East Asia and United States (Hseieh et al., 1977; Kuhlman, 1982; Puhalla and Spieth, 1985; Wulff et al., 2010; Petrovic et al., 2013).

**Alternate hosts:** Alternate hosts viz., tomato, cowpea, banana, subabool, proso millet, early water grass and barnyard grass have been found susceptible to bakanae disease and may also serve as reservoir of inoculum in the field (Anderson and Webster, 2005; Carter et al., 2008).

**Chemical seed treatment:** Currently, the seed treatment with chemicals is the most common management practice for bakanae disease in India (Gupta et al., 2014) and widely practiced in most of East Asia. Bagga and Sharma (2006) found seedling treatment with carbendazim or benlate (0.1%) for 6 and 8 h, significantly reduced the disease incidence up to 92%. Dip the seed in bavistin 50 WP (0.05%) plus streptocycline (0.01%) solution for 12 h and smearing the seeds with talc formulation of *Trichoderma harzianum* (15 g/kg seed) immediately before nursery sowing and seedling root dip for 6 hrs in *T. harzianum* biopowder (15 g/liter water) was found most effective against bakanae disease (Pannu et al., 2009). The research on bakanae disease and its sustainable management is need of hour and must be given top priority for disease free quality seed production, realizing higher yield potential of aromatic rice and to get edge in rice trade at international market before it is too late.

The technology gap, extension gap and technological index (Samui et al., 2000) were calculated by using following formula as given below equations [Eq. 1-4]:

<table>
<thead>
<tr>
<th>Percent increase yield=</th>
<th>Demonstration yield-farmers yield</th>
<th>Farmers yield</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>--------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td></td>
<td>Potential yield - Demonstrated yield</td>
<td>x 100</td>
</tr>
</tbody>
</table>

**Methods and materials**

The FLD was conducted to study the percent incidence of bakanae disease and gaps between potential yield and demonstration yield, extension gap and
technology index. Results of 20 frontline demonstrations conducted during kharif 2014 and 2015 in 8.0 ha area on farmer’s field of five villages of Ambala district indicated that the cultivation practices under FLDs viz. demonstrated high yielding basmati variety of rice (PB 1121). The basmati variety Pusa Basmati 1121, released from IARI (New Delhi) of 145 days duration which is sown in the first fortnight of June. Before nursery raising seeds was treated with Carbendazim @ 2.0g/kg of seed. About 25-30 days old seedling having 5 to 6 leaf stage was transplanted in first fortnight of July. Transplant two-three seedlings per hill in line at spacing of 20x15 cm (33 hills/sq. meters). The cultural practices were performed uniformly and equally to all the FLD plots. The crop was raised following standard agronomic practices of irrigation and Nitrogen (N\textsubscript{2}) and Phosphorus (P\textsubscript{2}O\textsubscript{5}) fertilizers were applied @ 90:30 kg/ha. All P\textsubscript{2}O\textsubscript{5} and 1/2 N\textsubscript{2} were applied at the time of transplanting and rest of N\textsubscript{2} were applied at panicle initiation stage. At booting stage one spray of Sixer (Mancozeb 63% + Carbendazim 12%) W.P. fungicide @ 600g/acre was applied and timely inter culturing operations like weeding and control of pest was followed through recommended chemicals at economic threshold level.

**Result and Discussion**

The average FLDs yield was recorded 41.12 and 43.25 q/ha during 2014 and 2015, respectively, which were found 14.22 and 15.33 per cent consequently, increased over local check. Percent incidence of bakanae disease was recorded minimum in FLD plots range 7 and 5 per cent during 2014 and 2015, respectively which were found maximum in local check range 19 and 12 per cent consequently during 2014 and 2015. Data further shows that the yield of PB 1121 in the year 2015 was increased successively which clearly speaks of the positive impact of FLD over local check of basmati rice (Table 1).

The results indicate that FLDs has given a good impact over farming communities of Ambala district as they were aware by the applying of one spray of sixer at booting stage of rice plant after following seed treatment strategy. It’s help to reduce disease incidence of bakanae. Moreover, from first year onwards, farmers cooperated enthusiastically in carrying out FLDs which leads to encouraging results in the second year. The similar results of yield enhancement in chick pea in front line demonstration had also documented by Singh et al (2014).

The technological gap 13.88 and 11.75 q/ha in the year 2014 and 2015, respectively showing cooperation of the farmer’s, for adopting such types of demonstrations which is help full to generate and encouraging results in subsequent year. The technology gap observed may be unavailability of specified fungicide for the management of bakanae disease at the time of occurrence and agro climatic conditions also responsible. The existing gap which ranged from 5.12 to 5.75 q/ha during the period of study emphasized the need to educate the farmers regarding how to recognize to the specified diseases and its effective management strategy, through conducting of on/off training programme on IDM, to organize plant health camping at village level and provide litterateurs also. All these extension activities help to the farmers for adapting to the new and improved agricultural technologies, that are reserve this trend of wide extension gap between farmers and technologies.

The technology index shows the feasibility of the evolved technology at the farmer’s field. The lowest value of technology index which indicate the more feasibility of the technology. As such, decreased the technology index from 25.24 to 21.36 per cent indicated that the demonstrated technology was feasible (Table 1).

The benefit cost ratio of the front line demonstration revealed that B:C ratio from recommended practice were subsequently higher than the local check i.e. farmers practices (Table 2).

During the data of both years of the demonstration plots. Average net return per hectare from the demonstration was Rs. 64,743.00 and Rs. 1,08208.00, while from the local check Rs. 50,812.00 and Rs. 92,200.00 during the 2014 and 2015, respectively. The benefit cost ratio of demonstration was found 3.58 and 4.42 while in local check 2.88 and 4.05 during the year 2014 and 2015, respectively. Similar finding was reported by Sharma (2003) in moth bean.

Conclusion

The present study of front line demonstrations produces a significant positive result and gives researchers an opportunity to demonstrate the effectiveness of management of bakanae disease by one spray of Sixer (Mancozeb 63% + Carbendazim 12%) W.P. fungicide at booting stage of rice plant after seed treatment. It’s also help to reduce per cent disease incidence of bakanae disease and enhance to the productivity potential and profitability of rice crop after adopting the recent developed technology under real farming situation, which they have advocating for long time. The results of front line demonstrations convincingly brought out that the yield of basmati rice verity (PB 1121) could be increased 14.22 per cent to 15.33 per cent and reduce disease incidence of bakanae 7 per cent to 5 per cent during year 2014 and 2015, respectively with intervention on one spraying of Sixer (Mancozeb 63% + Carbendazim 12%) W.P. fungicide at booting stage. From the above findings it can also concluded that use of one spraying strategy of fungicide at booting stage, after following seed treatment strategy reduced the extension and technology gap to a great extent. This will sustainably increase the income of the farmers of the Ambala district.
